Negative-weight cycles

Recall: If a graph $G = (V, E)$ contains a negative-weight cycle, then some shortest paths may not exist.

Example:

Bellman-Ford algorithm: Finds all shortest-path lengths from a **source** $s \in V$ to all $v \in V$ or determines that a negative-weight cycle exists.

Bellman-Ford and Undirected graphs

Bellman-Ford algorithm is designed for **directed** graphs.

If G is undirected, replace every edge (u, v) with two directed edges (u, v) and (v, u) , both with weight $w(u, v)$

Bellman-Ford algorithm

```

d[s] ← 0
for each v ∈ V - {s} } initialization
do d[v] ← ∞

for i ← 1 to |V| - 1 do
  for each edge (u, v) ∈ E do
    if d[v] > d[u] + w(u, v) then } relaxation
      d[v] ← d[u] + w(u, v) } step
      π[v] ← u

for each edge (u, v) ∈ E
  do if d[v] > d[u] + w(u, v)
     then report that a negative-weight cycle exists
    
```

At the end, $d[v] = \delta(s, v)$. Time = $O(|V| |E|)$.

Example of Bellman-Ford

Order of edges: $(B, E), (D, B), (B, D), (A, B), (A, C), (D, C), (B, C), (E, D)$

A	B	C	D	E
0	∞	∞	∞	∞

Note: Values decrease monotonically.

Correctness

Theorem. If $G = (V, E)$ contains no negative-weight cycles, then after the Bellman-Ford algorithm executes, $d[v] = \delta(s, v)$ for all $v \in V$.

Proof. Let $v \in V$ be any vertex, and consider a shortest path p from s to v with the minimum number of edges.

Since p is a shortest path, we have

$$\delta(s, v_i) = \delta(s, v_{i-1}) + w(v_{i-1}, v_i) \text{ for every } i.$$

Correctness (continued)

Initially, $d[v_0] = 0 = \delta(s, v_0)$, and $d[s]$ is unchanged by subsequent relaxations (because of the lemma from last lecture that $d[v] \geq \delta(s, v)$ and $\delta(s, s) \geq 0$ (why ?)).

- After 1 pass through E , we have $d[v_1] = \delta(s, v_1)$.
- After 2 passes through E , we have $d[v_2] = \delta(s, v_2)$.
-
- After k passes through E , we have $d[v_k] = \delta(s, v_k)$.

Since G contains no negative-weight cycles, p is simple. Longest simple path has $\leq |V| - 1$ edges. □

Detection of negative-weight cycles

Corollary. If a value $d[v]$ fails to converge after $|V| - 1$ passes, there exists a negative-weight cycle in G reachable from s . □

DAG shortest paths

If the graph is a **directed acyclic graph (DAG)**, we first **topologically sort** the vertices.

- Determine $f: V \rightarrow \{1, 2, \dots, |V|\}$ such that $(u, v) \in E \Rightarrow f(u) < f(v)$.
- $O(V + E)$ time using depth-first search.

Walk through the vertices $u \in V$ in this order, relaxing the edges in $Adj[u]$, thereby obtaining the shortest paths from s in a total of $O(V + E)$ time.
