A function is Higher-Order if it takes a function as an **CSc 372** argument or returns one as its result. Higher-order function aren't weird; the differentiation **Comparative Programming** operation from high-school calculus is higher-order: Languages deriv :: (Float->Float)->Float->Float 11 : Haskell — Higher-Order Functions deriv f x = (f(x+dx) - f x)/0.0001Christian Collberg Many recursive functions share a similar structure. We can capture such "recursive patterns" in a higher-order collberg+372@gmail.com function. Department of Computer Science We can often avoid the use of explicit recursion by University of Arizona using higher-order functions. This leads to functions that are shorter, and easier to read and maintain. Copyright © 2005 Christian Collberg [1] [2] -Fall 2005 — 11 372 — Fall 2005 — 11 **Currying Revisited Currying Revisited...** We have already seen a number of higher-order How is a curried function defined? • A curried function of *n* arguments (of types functions. In fact, any curried function is higher-order. Why? Well, when a curried function is applied to one of t_1, t_2, \dots, t_n) that returns a value of type t is defined its arguments it returns a new function as the result. like this: fun :: $t_1 \rightarrow t_2 \rightarrow \cdots \rightarrow t_n \rightarrow t$ Uh, what was this currying thing? • This is sort of like defining *n* different functions (one for A curried function does not have to be applied to all its each ->). In fact, we could define these functions arguments at once. We can supply some of the explicitly, but that would be tedious: arguments, thereby creating a new specialized function.

Higher-Order Functions

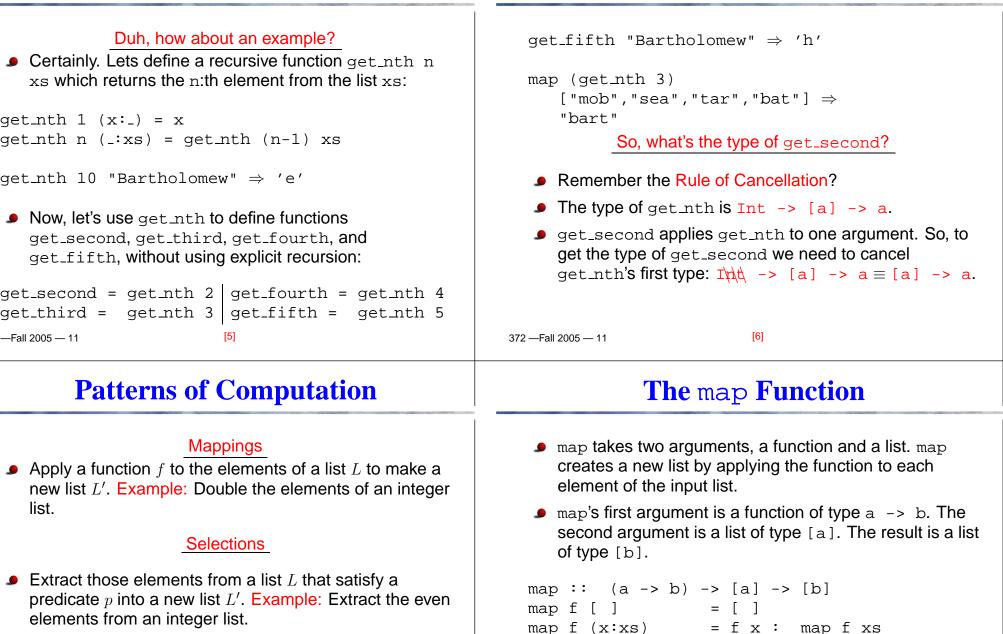

to a higher-order function.

[2]

This function can, for example, be passed as argument

Currying Revisited...

Currying Revisited...

Folds

Combine the elements of a list L into a single element using a binary function f. Example: Sum up the elements in an integer list. We can check the type of an object using the :type command. Example: :type map.

The filter Function...

fold **Functions...**

Haskell provides a function foldr ("fold right") which

captures this pattern of computation.

- foldr takes three arguments: a function, a seed value, $foldr(\oplus)z[x_1\cdots x_n] = (x_1 \oplus (x_2 \oplus (\cdots (x_n \oplus z))))$ and a list. Examples: Several functions in the standard prelude are defined using foldr: foldr (+) 0 $[1,2,3,4,5] \Rightarrow 15$ foldr (++) "" ["H","i","!"] ⇒ "Hi!" and, or :: [Bool] -> Bool foldr: and xs = foldr (&&) True xsfoldr :: (a->b->b) -> b -> [a] -> b or xs = foldr (||) False xsfoldr f z [] or [True, False, False] \Rightarrow ? foldr f z (x:xs) = f x (foldr f z xs) foldr (||) False [True, False, False] \Rightarrow True || (False || (False || False)) \Rightarrow True [17] 372 — Fall 2005 — 11 [18] —Fall 2005 — 11 fold **Functions...** fold **Functions...** Remember that foldr binds from the right: In the case of (+) and many other functions foldr (+) 0 $[1,2,3] \Rightarrow (1+(2+(3+0)))$ $foldl(\oplus)z[x_1\cdots x_n] = foldr(\oplus)z[x_1\cdots x_n]$ There is another function fold1 that binds from the left: However, one version may be more efficient than the foldl (+) 0 $[1,2,3] \Rightarrow (((0+1)+2)+3)$
- In general:

 $foldl(\oplus)z[x_1\cdots x_n] = (((z \oplus x_1) \oplus x_2) \oplus \cdots \oplus x_n)$

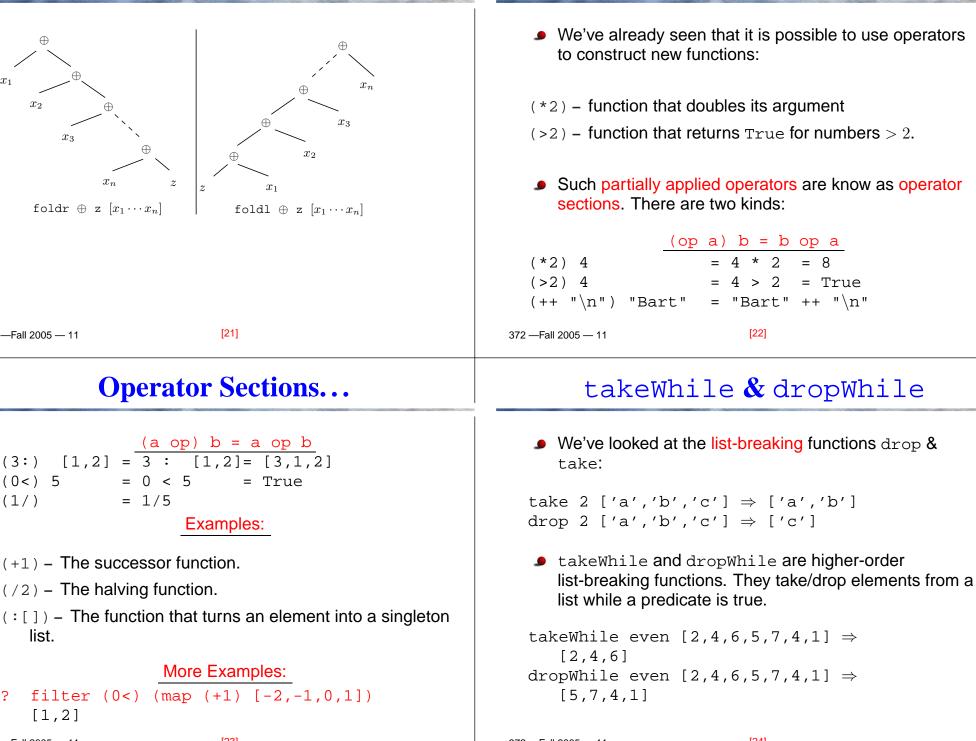

fold **Functions...**

Note how the fold process is started by combining the last element x_n with z. Hence the name seed.

other.

Operator Sections

Remove initial/final blanks from a string: takeWhile :: (a->Bool) -> [a] -> [a] takeWhile p[] = []dropWhile ((==) ', ') ", Hi!" \Rightarrow takeWhile p (x:xs) "Hi!" = x : takeWhile p xs рх otherwise = [] takeWhile ((/=) ',') "Hi!, "," \Rightarrow "Hi!" dropWhile :: (a->Bool) -> [a] -> [a] dropWhile p [] = [] dropWhile p (x:xs) = dropWhile p xs рх otherwise = x:xs [25] [26] —Fall 2005 — 11 372 — Fall 2005 — 11 Summary... **Summary** Higher-order functions take functions as arguments, or The standard prelude contains many useful return a function as the result. higher-order functions: map f xs creates a new list by applying the function f to We can form a new function by applying a curried every element of a list xs. function to some (but not all) of its arguments. This is called partial application. filter p xs creates a new list by selecting only those elements from xs that satisfy the predicate p (i.e. (p Operator sections are partially applied infix operators. x) should return True). foldr f z xs reduces a list xs down to one element, by applying the binary function f to successive elements, starting from the right. scanl/scanr f z xs perform the same functions as foldr/foldl, but instead of returning only the ultimate value they return a list of all intermediate results. [07] [00]

takeWhile & dropWhile...

 If the lists are of unequal length, an error should be returned.

Examples:

zipp (+) [1,2,3] $[4,5,6] \Rightarrow [5,7,9]$

sipp (==) [1,2,3] $[4,2,2] \Rightarrow$ [False,True,True]

 $zipp (==) [1,2,3] [4,2] \Rightarrow ERROR$

xs that removes the last occurence of an element of xs without the property p. Example: filterLast even $\begin{bmatrix} 2 & 4 & 6 & 5 & 6 & 8 & 7 \end{bmatrix} \Rightarrow$

Use filterFirst to define a function filterLast p

[20]

```
filterLast even [2,4,6,5,6,8,7] \Rightarrow [2,4,6,5,6,8]
```

filterFirst even $[2,4,6,5,6,8,7] \Rightarrow$

[2,4,6,6,8,7]

[21]
