## Don't Evaluate Until Necessary

## Don't Evaluate Until Necessary...

- The first of these ideas is illustrated by the following function:

```
ignoreArgument x = "I didn't evaluate x"
```

- Since the result of the function ignoreArgument doesn't depend on the value of its argument x , that argument will not be evaluated:

```
$ hugs +s
> ignoreArgument (1/0)
I didn't evaluate x
(246 reductions, 351 cells)
```

- The function seq forces strict evaluation when that is necessary:

```
> seq ignoreArgument (1/0)
Inf
(32 reductions, 78 cells)
```

## Evaluate Shared Expressions Once

- The second basic idea behind lazy evaluation is that no shared expression should be evaluated more than once.
- For example, the following two expressions can be used to calculate $3 * 3 * 3 * 3$ :

```
$ hugs +s
> square*square where square = 3*3
81
(30 reductions, 67 cells)
> (3* 3)* (3*3)
81
(34 reductions, 45 cells)
```

## Saving Reductions

- Consider these sequences of reductions:

```
square * square where square = 3 * 3
    -- calculate the value of square by
    -- reducing 3*3==>9 and replace each
    -- occurrence of square with this result
    ==> 9 * 9
    ==> 81
(3 * 3) * (3 * 3) -- evaluate first (3* 3)
    ==> 9 * (3 * 3) -- evaluate second (3*3)
    ==> 9 * 9
    ==> 81
```

- Lazy evaluation means that only the minimum amount of calculation is used to determine the result of an expression.
- Notice that the first expression requires fewer reduction than the second.
- A reduction is the basic step of evaluating a Haskell expression, by applying a function to its argument.

## Taking the Minimum

- Consider the task of finding the smallest element of a list of integers.

```
> minimum [100,99..1]
1
(2355 reductions, 3211 cells)
```

- $[100,99 \ldots 1]$ denotes the list of integers from 1 to 100 arranged in decreasing order.
- Instead, we could first sort and then take the head of the result:

```
> :load List
> sort [100,99..1]
[1, 2, 3, 4, 5, 6, 7, 8, ..., 99, 100]
(3430 reductions, 8234 cells)
```

## Taking the Minimum. .

Infinite data structures

- However, thanks to lazy evaluation, calculating just the first element of the sorted list actually requires less work in this particular case than the first solution using minimum:

```
> head (sort [100,99..1])
1
(1877 reductions, 3993 cells)
> minimum [100,99..1]
1
(2355 reductions, 3211 cells)
```

## Infinite data structures...

- Consider the following function which can be used to produce infinite lists of integer values:

```
countFrom n = n : countFrom (n+1)
```

> countFrom 1
$\left[1,2,3,4,5,6,7,8,{ }^{\wedge}\right.$ CInterrupted!]

- Lazy evaluation makes it possible for functions in Haskell to manipulate 'infinite' data structures.
- The advantage of lazy evaluation is that it allows us to construct infinite objects piece by piece as necessary
- The function ones below generates an infinite list of 1 s :

```
ones = 1 : ones
> take 10 ones
[1,1,1,1,1,1,1,1,1,1]
(277 reductions, 389 cells)
```

372 -Fall 2005-14
[10]

## Infinite data structures...

- For practical applications, we are usually only interested in using a finite portion of an infinite data structure.
- We can find the sum of the integers 1 to 10 :

```
> sum (take 10 (countFrom 1))
5
(278 reductions, 440 cells)
```

- take $n$ xs evaluates to a list containing the first $n$ elements of the list xs.

## Infinite data structures.

- xs!!n evaluates to the $n$ :th element of the list xs .
- We can define a function to find the $n$th power of 2 for any given integer $n$ :

```
powersOfTwo = 1 : map (*2) powersOfTwo
twoToThe n = powersOfTwo !! n
> twoToThe 5
32
```
