# Procedure Declarations

- A procedure has five parts: The heading, local declarations, initializations, static declarations, and the procedure body.
- A variable that is declared **static survives** between procedure invocations.
- Statements in an **initial** clause are run **the first time** the procedure is called.

```
global R, T
procedure name (arguments, extra[ ] )
    local x, y, z
    static a, b, c
    initial { ... }
    <statements>
end
```

# Procedure Declarations...

```
procedure foo()
    static counter
    initial {counter:=1}
    ...
    counter :+= 1
end
```

# Parameter Passing

- Parameters are called **by value**.
- This means that actual arguments to a procedure are copied into the formal parameters.
- Any changes to the formals won't affect any of the actuals. This is similar to C and Java.

```
procedure foo(a)
  a := "bye"
end
```

```
procedure main()
  local a
  a := "hello"
  foo(a)
  write(a)
end
```

# Modules

- Note that Icon doesn't have a real module-system.
- All names (procedure names, record names, global variables) live in the same **name space**.
- You need to make sure that all global names are unique! I usually do this by prefixing all names by the module-name: `mymodule_myproc`.

# Formal Parameters

- When you call a procedure you can supply fewer arguments than there are formal parameters:

```
procedure P (f1, f2, f3)  
end
```

When calling `P` with `P(a1, a2)` the formal parameter `f1` will take on the value of `a1`, and `f2` will get `a2`. `f3` will become `null`.

# Default Parameters

- A common idiom for default parameters:

```
procedure P (f1, f2, f3)
    /f3 := <default value>
end
```

- When calling **P** with **P(a1, a2)**, **f3** will get the default value.
- When calling **P** with **P(a1, a2, a3)**, **f3** will get the value of **a3**.

# Arbitrary Length Argument Lists

- Icon supports arbitrary length argument lists:

```
procedure P (f1, f2, f3[])
end
```

When calling `P` with `P(a1, a2, a3, a4, a5)`, the `f3` formal will hold the list `[a3, a4, a5]`.

# Procedure Returns

- `return e` returns the value `e`.
- If `e` in `return e` fails, then the procedure call itself fails.

```
procedure less(a)
    return a<10
end
```

```
][ .inc less.inc
][ less(5);
    r1 := 10
][ less(100);
Failure
```

# Indirect Procedure Calls

- Procedure names can be constructed at runtime, allowing a powerful form of indirect procedure call.
- Remember to include the directive `invokable all` at the beginning of your module.
- `proc(P)` returns the procedure whose name is the string `P`.

```
P1 := proc("MyProc1")  
P2 := proc("MyProc" || "2")  
P3 := proc("find")           # Built-ins OK, too.  
P4 := proc("*", 2)          # Multiplication has arity 2.  
L := [P1, P2, P3, P4]       # A list of procedures.  
L[2](45, "X2")             # Calling MyProc2(45, "X2").
```
