Higher-Order Functions

101 (B) (2) (2) (2) 2 000

Currying Revisited

 We have already seen a number of higher-order functions. In fact, any curried function is higher-order. Why? Well, when a curried function is applied to one of its arguments it returns a new function as the result.

Uh, what was this currying thing?

 A curried function does not have to be applied to all its arguments at once. We can supply some of the arguments, thereby creating a new specialized function. This function can, for example, be passed as argument to a higher-order function.

- A function is Higher-Order if it takes a function as an argument or returns one as its result.
- Higher-order function aren't weird; the differentiation operation from high-school calculus is higher-order:

deriv :: (Float->Float)->Float->Float
deriv f x = (f(x+dx) - f x)/0.0001

- Many recursive functions share a similar structure. We can capture such "recursive patterns" in a higher-order function.
- We can often avoid the use of explicit recursion by using higher-order functions. This leads to functions that are shorter, and easier to read and maintain.

Currying Revisited...

How is a curried function defined?

 A curried function of n arguments (of types t₁, t₂, ..., t_n) that returns a value of type t is defined like this:

fun :: $t_1 \rightarrow t_2 \rightarrow \cdots \rightarrow t_n \rightarrow t$

This is sort of like defining n different functions (one for each ->). In fact, we could define these functions explicitly, but that would be tedious:

```
fun_1 :: t_2 \rightarrow \cdots \rightarrow t_n \rightarrow t
fun_1 a_2 \cdots a_n = \cdots
```

```
fun_2 :: t_3 \rightarrow \cdots \rightarrow t_n \rightarrow t
fun_2 a_3 \cdots a_n = \cdots
```

Currving Revisited...

Currving Revisited...

command. Example: :type map.

Dub, how about an example? • Certainly. Lets define a recursive function get_nth n xs get_fifth "Bartholomew" ⇒ 'h' which returns the n:th element from the list xs: map (get nth 3) get_nth 1 (x:_) = x ["mob","sea","tar","bat"] ⇒ get_nth n (:xs) = get_nth (n-1) xs "bart" get_nth 10 "Bartholomew" ⇒ 'e' So, what's the type of get_second? Remember the Rule of Cancellation? Now, let's use get nth to define functions get second, • The type of get_nth is Int -> [a] -> a. get_third, get_fourth, and get_fifth, without using get_second applies get_nth to one argument. So, to get the explicit recursion: type of get_second we need to cancel get_nth's first type: get second = get nth 2 get fourth = get nth 4 Int -> [a] -> $a \equiv [a] \rightarrow a$. get third = get nth 3 get fifth = get nth 5 100 COL 100 COL 100 COL 100 COL 101 121 121 2 000 Patterns of Computation The map Function Mappings _____ map takes two arguments, a function and a list. map creates a new list by applying the function to each element of the input Apply a function f to the elements of a list L to make a new list. list L'. Example: Double the elements of an integer list. map's first argument is a function of type a -> b. The second Selections argument is a list of type [a]. The result is a list of type [b]. Extract those elements from a list L that satisfy a predicate p into a new list L'. Example: Extract the even elements from map :: $(a \rightarrow b) \rightarrow [a] \rightarrow [b]$ an integer list. map f [] = [] Folds map f (x:xs) = f x : map f xs Combine the elements of a list L into a single element using a binary function f. Example: Sum up the elements in an We can check the type of an object using the :type integer list.

The map Function...

The map Function...

The filter Function

____ Simulation: _____

```
map square [5,6] ⇒
square 5 : map square [6] ⇒
25 : map square [6] ⇒
25 : (square 6 : map square []) ⇒
25 : (36 : map square []) ⇒
25 : (36 : []) ⇒
25 : [36] ⇒
[25,36]
```

- Filter takes a predicate p and a list L as arguments. It returns a list L' consisting of those elements from L that satisfy p.
- The predicate p should have the type a -> Bool, where a is the type of the list elements.

Examples:

filter even $[1..10] \Rightarrow [2,4,6,8,10]$ filter even (map square $[2..5]) \Rightarrow$ filter even $[4,9,16,25] \Rightarrow [4,16]$ filter gt10 [2,5,9,11,23,114]where gt10 x = x > 10 $\Rightarrow [11,23,114]$

The filter Function...

The filter Function...

 We can define filter using either recursion or list comprehension.

Using recursion:

Using list comprehension:

filter :: (a \rightarrow Bool) \rightarrow [a] \rightarrow [a] filter p xs = [x | x <- xs, p x]

The filter Function...

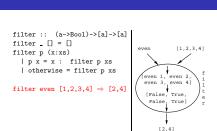

fold Functions

 A common operation is to combine the elements of a list into one element. Such operations are called reductions or accumulations.

Examples:

 $\begin{array}{l} \text{sum } [1,2,3,4,5] \equiv \\ (1+(2+(3+(4+(5+0))))) \Rightarrow 15 \\ \text{concat } ["\text{H"},"i","i"] \equiv \\ ("\text{H"} ++("i" ++("!" ++""))) \Rightarrow "\text{Hi!"} \end{array}$

 Notice how similar these operations are. They both combine the elements in a list using some binary operator (+, ++), starting out with a "seed" value (0, "").

101 (B) (2) (2) (2) 2 000

fold Functions...

fold Functions...

- Haskell provides a function foldr ("fold right") which captures this pattern of computation.
- foldr takes three arguments: a function, a seed value, and a list.

Examples:

foldr (+) 0 [1,2,3,4,5] ⇒ 15
foldr (++) "" ["H","i","!"] ⇒ "Hi!"

foldr:

foldr :: (a->b->b) -> b -> [a] -> b foldr f z [] = z foldr f z (x:xs) = f x (foldr f z xs) • Note how the fold process is started by combining the last element x_n with z. Hence the name seed.

 $foldr(\oplus)z[x_1\cdots x_n] = (x_1 \oplus (x_2 \oplus (\cdots (x_n \oplus z))))$

• Several functions in the standard prelude are defined using foldr:

and,or :: [Bool] -> Bool and xs = foldr (&&) True xs or xs = foldr (||) False xs

? or [True,False,False] ⇒
foldr (||) False [True,False,False] ⇒
True || (False || (False || False)) ⇒ True

900 S (S) (S) (S) (S)

fold Functions...

fold Functions...

Remember that foldr binds from the right:

foldr (+) 0 $[1,2,3] \Rightarrow (1+(2+(3+0)))$

There is another function foldl that binds from the left:

foldl (+) 0 $[1,2,3] \Rightarrow (((0+1)+2)+3)$

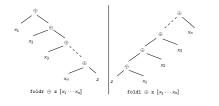

In general:

 $foldl(\oplus)z[x_1\cdots x_n] = (((z \oplus x_1) \oplus x_2) \oplus \cdots \oplus x_n)$

. In the case of (+) and many other functions

$$foldl(\oplus)z[x_1\cdots x_n] = foldr(\oplus)z[x_1\cdots x_n]$$

. However, one version may be more efficient than the other.

- · We've already seen that it is possible to use operators to construct new functions:
 - (*2) function that doubles its argument
 - (>2) function that returns True for numbers > 2.
- Such partially applied operators are know as operator sections. There are two kinds:

	(op a) b = b op a
(*2) 4	= 4 * 2 = 8
(>2) 4	= 4 > 2 = True
(++ "\n") "Bart"	= "Bart" ++ "\n"

Operator Sections...

takeWhile & dropWhile

(a op) b = a op b _____ (3:) [1,2] = 3: [1,2] = [3,1,2](0<) 5 = 0 < 5 = True (1/)= 1/5

Examples:

- (+1) The successor function.
- (/2) The halving function.
- (:[]) The function that turns an element into a singleton list

More Examples:

? filter (0<) (map (+1) [-2,-1,0,1]) [1.2]

- - We've looked at the list-breaking functions drop & take:

take 2 ['a','b','c'] ⇒ ['a','b'] drop 2 ['a', 'b', 'c'] \Rightarrow ['c']

takeWhile and dropWhile are higher-order list-breaking functions. They take/drop elements from a list while a predicate is true.

takeWhile even $[2.4, 6.5, 7, 4.1] \Rightarrow$ [2.4.6] dropWhile even [2,4,6,5,7,4,1] ⇒ [5.7.4.1]

takeWhile & dropWhile...

```
Remove initial/final blanks from a string:
```

```
dropWhile ((==) '∟') "⊔⊔⊔Hi!" ⇒
"Hi!"
```

takeWhile ((/=) '_') "Hi!____" \Rightarrow "Hi!"

900 S (S) (S) (S) (S)

Summary

Summary...

- The standard prelude contains many useful higher-order functions:
 - map f xs creates a new list by applying the function f to every element of a list xs.
 - filter p xs creates a new list by selecting only those elements from xs that satisfy the predicate p (i.e. (p x) should return True).
 - foldr f z xs reduces a list xs down to one element, by applying the binary function f to successive elements, starting from the right.
 - scanl/scanr f z xs perform the same functions as foldr/foldl, but instead of returning only the ultimate value they return a list of all intermediate results.

Higher-order functions take functions as arguments, or return a function as the result.

- We can form a new function by applying a curried function to some (but not all) of its arguments. This is called partial application.
- Operator sections are partially applied infix operators.
