1 Higher-Order Functions

- A function is Higher-Order if it takes a function as an argument or returns one as its result.
- Higher-order function aren't weird; the differentiation operation from high-school calculus is higher-order:

```
deriv :: (Float->Float)->Float->Float
deriv f x = (f(x+dx) - f x)/0.0001
```

- Many recursive functions share a similar structure. We can capture such "recursive patterns" in a higher-order function.
- We can often avoid the use of explicit recursion by using higher-order functions. This leads to functions that are shorter, and easier to read and maintain.

2 Currying Revisited

•	 We have already seen a number of higher-order functions. In fact, any curried function is high 	gher-order.
	Why? Well, when a curried function is applied to one of its arguments it returns a new f	iunction as
	the result.	

 Uh, what was this currying thing	?

• A curried function does not have to be applied to all its arguments at once. We can supply some of the arguments, thereby creating a new specialized function. This function can, for example, be passed as argument to a higher-order function.

3 Currying Revisited...

How is a curried function defined	?

• A curried function of n arguments (of types t_1, t_2, \dots, t_n) that returns a value of type t is defined like this:

```
fun :: t_1 \rightarrow t_2 \rightarrow \cdots \rightarrow t_n \rightarrow t
```

• This is sort of like defining n different functions (one for each ->). In fact, we could define these functions explicitly, but that would be tedious:

4 Currying Revisited...

ullet Certainly. Lets define a recursive function ${\tt get_nth}$ n ${\tt xs}$ which returns the ${\tt n:th}$ element from the list

_____ Duh, how about an example? _____

```
get_nth 1 (x:_) = x
get_nth n (_:xs) = get_nth (n-1) xs
get_nth 10 "Bartholomew" \( \Rightarrow \cdot \epsilon \cdot \epsilon \cdot \epsilon \cdot \epsilon \cdot \epsilon \epsilon \cdot \epsilon \cdot \epsilon \cdot \epsilon \epsilo
```

• Now, let's use get_nth to define functions get_second, get_third, get_fourth, and get_fifth, without using explicit recursion:

```
get_second = get_nth 2 | get_fourth = get_nth 4
get_third = get_nth 3 | get_fifth = get_nth 5
```

5 Currying Revisited...

```
get_fifth "Bartholomew" \Rightarrow 'h'
map (get_nth 3)
    ["mob","sea","tar","bat"] \Rightarrow
"bart"
```

So, what's the type of get_second?

- Remember the Rule of Cancellation?
- The type of get_nth is Int -> [a] -> a.
- get_second applies get_nth to one argument. So, to get the type of get_second we need to cancel get_nth's first type: \textstyre: \textstyre \textstyre

6 Patterns of Computation

____ Mappings _____

• Apply a function f to the elements of a list L to make a new list L'. Example: Double the elements of an integer list.

Selections _____

• Extract those elements from a list L that satisfy a predicate p into a new list L'. Example: Extract the even elements from an integer list.

 \longrightarrow Folds \longrightarrow

• Combine the elements of a list L into a single element using a binary function f. Example: Sum up the elements in an integer list.

7 The map Function

- map takes two arguments, a function and a list. map creates a new list by applying the function to each element of the input list.
- map's first argument is a function of type a -> b. The second argument is a list of type [a]. The result is a list of type [b].

```
map :: (a -> b) -> [a] -> [b]
map f [] = []
map f (x:xs) = f x : map f xs
```

• We can check the type of an object using the :type command. Example: :type map.

8 The map Function...

map ::
$$(a \rightarrow b) \rightarrow [a] \rightarrow [b]$$

map f [] = []
map f (x:xs)= f x : map f xs
inc x = x + 1
map inc [1,2,3,4] \Rightarrow [2,3,4,5]
[inc 1,inc 2,inc 3,inc 4]

9 The map Function...

map f[] = [] means: "The result of applying the function f to the elements of an empty list is the empty list."

map f(x:xs) = fx : map fxs means: "applying f to the list (x:xs) is the same as applying f to x (the first element of the list), then applying f to the list xs, and then combining the results."

10 The map Function...

_____ Simulation: _____

```
map square [5,6] \Rightarrow
square 5 : map square [6] \Rightarrow
25 : map square [6] \Rightarrow
25 : (square 6 : map square []) \Rightarrow
25 : (36 : map square []) \Rightarrow
25 : (36 : []) \Rightarrow
25 : [36] \Rightarrow
[25,36]
```

11 The filter Function

- Filter takes a predicate p and a list L as arguments. It returns a list L' consisting of those elements from L that satisfy p.
- The predicate p should have the type a -> Bool, where a is the type of the list elements.

Examples:

```
filter even [1..10] \Rightarrow [2,4,6,8,10]
filter even (map square [2..5]) \Rightarrow
filter even [4,9,16,25] \Rightarrow [4,16]
filter gt10 [2,5,9,11,23,114]
where gt10 x = x > 10 \Rightarrow [11,23,114]
```

12 The filter Function...

• We can define filter using either recursion or list comprehension.

_____ Using recursion: _____

Using list comprehension:

```
filter :: (a \rightarrow Bool) \rightarrow [a] \rightarrow [a]
filter p xs = [x \mid x \leftarrow xs, p x]
```

13 The filter Function...

```
filter :: (a->Bool)->[a]->[a]
filter _ [] = []
filter p (x:xs)
    | p x = x : filter p xs
    | otherwise = filter p xs
filter even [1,2,3,4] ⇒ [2,4]

filter even [1,2,3,4] ⇒ [2,4]

[False, True, False, True]
    | False, True]
    | False, True |
```

14 The filter Function...

• doublePos doubles the positive integers in a list.

_____Simulations: _____

```
getEven [1,2,3] \Rightarrow [2]

doublePos [1,2,3,4] \Rightarrow

map dbl (filter pos [1,2,3,4]) \Rightarrow

map dbl [2,4] \Rightarrow [4,8]
```

15 fold Functions

• A common operation is to combine the elements of a list into one element. Such operations are called reductions or accumulations.

Examples:

```
sum [1,2,3,4,5] \equiv (1 + (2 + (3 + (4 + (5 + 0))))) \Rightarrow 15

concat ["H","i","!"] \equiv ("H" ++ ("i" ++ ("!" ++ ""))) \Rightarrow "Hi!"
```

• Notice how similar these operations are. They both combine the elements in a list using some binary operator (+, ++), starting out with a "seed" value (0, "").

16 fold Functions...

- Haskell provides a function foldr ("fold right") which captures this pattern of computation.
- foldr takes three arguments: a function, a seed value, and a list.

Examples: foldr (+) 0 [1,2,3,4,5] ⇒ 15 foldr (++) "" ["H","i","!"] ⇒ "Hi!" foldr: foldr: foldr :: (a->b->b) -> b -> [a] -> b foldr f z [] = z foldr f z (x:xs) = f x (foldr f z xs)

17 fold Functions...

• Note how the fold process is started by combining the last element x_n with z. Hence the name seed.

$$\mathtt{foldr}(\oplus)\mathtt{z}[\mathtt{x}_1\cdots\mathtt{x}_n] = (\mathtt{x}_1\oplus(\mathtt{x}_2\oplus(\cdots(\mathtt{x}_n\oplus\mathtt{z}))))$$

• Several functions in the standard prelude are defined using foldr:

```
and,or :: [Bool] -> Bool
and xs = foldr (&&) True xs
or xs = foldr (||) False xs

? or [True,False,False] ⇒
  foldr (||) False [True,False,False] ⇒
  True || (False || (False || False)) ⇒ True
```

18 fold Functions...

• Remember that foldr binds from the right:

```
foldr (+) 0 [1,2,3] \Rightarrow (1+(2+(3+0)))
```

• There is another function fold1 that binds from the left:

```
foldl (+) 0 [1,2,3] \Rightarrow (((0+1)+2)+3)
```

• In general:

$$foldl(\oplus)z[x_1\cdots x_n] = (((z \oplus x_1) \oplus x_2) \oplus \cdots \oplus x_n)$$

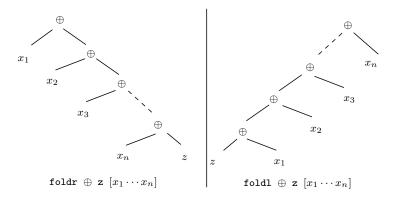

19 fold Functions...

• In the case of (+) and many other functions

$$\mathtt{foldl}(\oplus)\mathtt{z}[\mathtt{x}_1\cdots\mathtt{x}_n] = \mathtt{foldr}(\oplus)\mathtt{z}[\mathtt{x}_1\cdots\mathtt{x}_n]$$

• However, one version may be more efficient than the other.

20 fold Functions...

21 Operator Sections

- We've already seen that it is possible to use operators to construct new functions:
- (*2) function that doubles its argument
- (>2) function that returns True for numbers > 2.
 - Such partially applied operators are known as operator sections. There are two kinds:

____ (op a) b = b op a ____

$$(>2)$$
 4 = 4 > 2 = True

$$(++ "\n") "Bart" = "Bart" ++ "\n"$$

22 Operator Sections...

____ (a op) b = a op b_____

$$(3:)$$
 $[1,2] = 3:$ $[1,2] = [3,1,2]$

$$(0<) 5 = 0 < 5 = True$$

$$(1/) 5 = 1/5$$

Examples:

- (+1) The successor function.
- (/2) The halving function.
- (:[]) The function that turns an element into a singleton list.

_____ More Examples: _____

23 takeWhile & dropWhile

• We've looked at the list-breaking functions drop & take:

```
take 2 ['a','b','c'] \Rightarrow ['a','b'] drop 2 ['a','b','c'] \Rightarrow ['c']
```

• takeWhile and dropWhile are higher-order list-breaking functions. They take/drop elements from a list while a predicate is true.

```
takeWhile even [2,4,6,5,7,4,1] \Rightarrow [2,4,6] dropWhile even [2,4,6,5,7,4,1] \Rightarrow [5,7,4,1]
```

24 takeWhile & dropWhile...

25 takeWhile & dropWhile...

• Remove initial/final blanks from a string:

```
dropWhile ((==) '□') "□□□Hi!" ⇒
   "Hi!"

takeWhile ((/=) '□') "Hi!□□□" ⇒
   "Hi!"
```

26 Summary

- Higher-order functions take functions as arguments, or return a function as the result.
- We can form a new function by applying a curried function to some (but not all) of its arguments. This is called partial application.
- Operator sections are partially applied infix operators.

27 Summary...

• The standard prelude contains many useful higher-order functions:

map f xs creates a new list by applying the function f to every element of a list xs.

filter p xs creates a new list by selecting only those elements from xs that satisfy the predicate p (i.e. (p x) should return True).

foldr f z xs reduces a list xs down to one element, by applying the binary function f to successive elements, starting from the right.

scanl/scanr f z xs perform the same functions as foldr/foldl, but instead of returning only the ultimate value they return a list of all intermediate results.

Homework 28

Homework (a):
• Define the map function using a list comprehension.
Template:
$map\ f\ x = [\ \cdots\ \ \cdots\]$
Homework (b):
• Use map to define a function lengthall xss which takes a list of strings xss as argument and return a list of their lengths as result.
Examples:
<pre>? lengthall ["Ay", "Caramba!"] [2,8]</pre>
29 Homework
1. Give a accumulative recursive definition of foldl.

- 2. Define the minimum xs function using foldr.
- 3. Define a function sumsq n that returns the sum of the squares of the numbers $[1 \cdots n]$. Use map and foldr.
- 4. What does the function mystery below do?

```
mystery xs =
  foldr (++) [] (map sing xs)
sing x = [x]
                                 ____ Examples: ___
```

minimum $[3,4,1,5,6,3] \Rightarrow 1$

30 Homework...

- Define a function zipp f xs ys that takes a function f and two lists $xs=[x_1, \dots, x_n]$ and $ys=[y_1, \dots, y_n]$ as argument, and returns the list $[f x_1 y_1, \dots, f x_n y_n]$ as result.
- If the lists are of unequal length, an error should be returned.

_____Examples: _____

zipp (+)
$$[1,2,3]$$
 $[4,5,6] \Rightarrow [5,7,9]$

zipp (==)
$$[1,2,3]$$
 $[4,2,2] \Rightarrow [False,True,True]$

zipp (==)
$$[1,2,3]$$
 $[4,2] \Rightarrow ERROR$

31 Homework

• Define a function filterFirst p xs that removes the first element of xs that does not have the property p.

Example:

filterFirst even
$$[2,4,6,5,6,8,7] \Rightarrow [2,4,6,6,8,7]$$

• Use filterFirst to define a function filterLast p xs that removes the last occurrence of an element of xs without the property p.

Example:

filterLast even $[2,4,6,5,6,8,7] \Rightarrow [2,4,6,5,6,8]$
