Introduction

Unification & Matching

- So far, when we've gone through examples, I have said simply that when trying to satisfy a goal, Prolog searches for a matching rule or fact.
- What does this mean, to match?
- Prolog's matching operator or =. It tries to make its left and right hand sides the same, by assigning values to variables.
- Also, there's an implicit = between arguments when we try to match a query

to a rule

f(A,B) :-

```
deriv(U+V, X, DU + DV) :-
   deriv(U, X, DU),
   deriv(V, X, DV).
```

```
?- deriv(x^3 + x^2 + 1, x, D).
D = 1*3*x^2+1*2*x^1+0
```

```
    x ^3 + x^2 + 1 matches U + V
    x ^3 + x^2 is bound to U
    1 is bound to V
```

Can two terms A and F be "made identical," by assigning values to their variables?

Two terms A and F match if

- they are identical atoms
- One or both are uninstantiated variables
- 3 they are terms $A = f_A(a_1, \dots, a_n)$ and $F = f_F(f_1, \dots, f_m)$, and
 - the arities are the same (n = m)
 - ② the functors are the same $(f_A = f_F)$
 - (a) the arguments match $(a_i \equiv f_i)$

Matching – Examples

A	F	$A \equiv F$	variable subst.
а	а	yes	
а	b	no	
sin(X)	sin(a)	yes	$\theta = \{X=a\}$
sin(a)	sin(X)	yes	$\theta = \{X=a\}$
cos(X)	sin(a)	no	
sin(X)	sin(cos(a))	yes	$\theta = \{X = \cos(a)\}$

A	F	$A \equiv F$	variable subst.
likes(c, X)	likes(a, X)	no	
likes(c, X)	likes(c, Y)	yes	$\theta = \{X=Y\}$
likes(X, X)	likes(c, Y)	yes	$\theta = \{X=c, X=Y\}$
likes(X, X)	likes(c, _)	yes	$\theta = \{X=c, X=-47\}$
likes(c, a(X))	likes(V, Z)	yes	$\theta = \{V{=}c, Z{=}a(X)\}$
likes(X, a(X))	likes(c, Z)	yes	$\boldsymbol{\theta} = \{\mathbf{X}{=}\mathbf{c}{,}\mathbf{Z}{=}\mathbf{a}(\mathbf{X})\}$

Consequences of Prolog Matching:

- An uninstantiated variable will match any object.
- An integer or atom will match only itself.
- When two uninstantiated variables match, they share:
 - When one is instantiated, so is the other (with the same value).
- Backtracking undoes all variable bindings.

FUNC Unify (A, F: term) : BOOL;

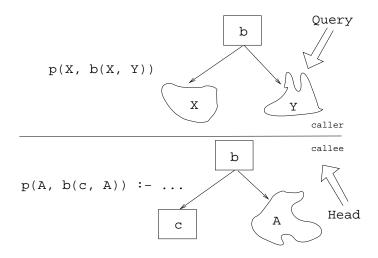

- IF Is_Var(F) THEN Instantiate F to A
- ELSIF Is_Var(A) THEN Instantiate A to F
- **ELSIF** Arity(F) ≠ Arity(A) **THEN RETURN** FALSE
- **ELSIF** Functor(F)≠Functor(A) **THEN RETURN** FALSE **ELSE**

FOR each argument i DO
IF NOT Unify(A(i), F(i)) THEN

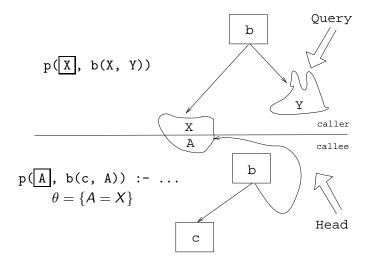

RETURN FALSE

RETURN TRUE;

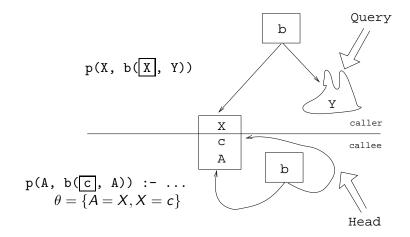

- From *Prolog for Programmers*, Kluzniak & Szpakowicz, page 18.
- Assume that during the course of a program we attempt to match the goal p(X, b(X, Y)) with a clause C, whose head is p(X, b(X, y)).
- First we'll compare the arity and name of the functors. For both the goal and the clause they are 2 and p, respectively.

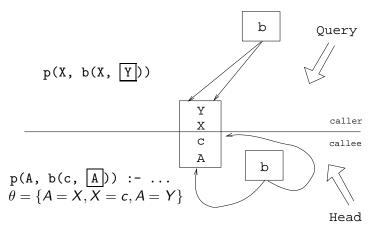

- The second step is to try to unify the first argument of the goal (X) with the first argument of the clause head (A).
- They are both variables, so that works OK.
- From now on A and X will be treated as identical (they are in the list of variable substitutions θ).

- Next we try to match the second argument of the goal (b(X, Y)) with the second argument of the clause head (b(c, A)).
- The arities and the functors are the same, so we go on to to try to match the arguments.
- The first argument in the goal is X, which is matched by the first argument in the clause head (c). I.e., X and c are now treated as identical.

• Finally, we match A and Y. Since A=X and X=c, this means that Y=c as well.

Summary

Readings and References

• Read Clocksin-Mellish, Sections 2.4, 2.6.3.

Prolog So Far...

- A term is either a
 - a constant (an atom or integer)
 - a variable
 - a structure
- Two terms *match* if
 - $\bullet\,$ there exists a variable substitution θ which makes the terms identical.
- Once a variable becomes instantiated, it stays instantiated.
- Backtracking undoes variable instantiations.
- Prolog searches the database sequentially (from top to bottom) until a matching clause is found.
