Write a procedure islist which succeeds if its argument is a list, and fails otherwise.

Write a procedure alter which changes English sentences according to rules given in the database. Example:

```
change(you, i).
change(are, [am, not]).
change(french, german).
change(do, no).
?- alter([do,you,know,french],X).
    X = [no,i,know,german]
?- alter([you,are,a,computer],X).
    X = [i,[am,not],a,computer]
```

Write a list subtraction procedure. Example:

Write a procedure pick which returns the first ${\tt N}$ elements of a given list. Example:

Write a procedure alt which produces every other element in a list. Example:

Write a procedure del which removes duplicate elements from a list. Example:

Write a procedure tolower which converts an atom containing upper case characters to the corresponding atom with only lower case characters.

Example:

Write a procedure max3 which produces the largest of three integers. Example:

Write a procedure double which multiplies each element in a list of numbers by 2. Example:

Write a procedure ave which computes the average of a list of numbers. Example:

Write a procedure sum which produces the sum of the integers up to and including its first argument. Example:

> ?- sum(5, S). S = 15

Suppose our database contains facts of the form

person_age(Name, Age).
person_sex(Name, Sex).

where Sex is either male or female. Write a procedure combine which extends the database with additional facts of the form

```
person_full(Name, Age, Sex).
```

The procedure should produce one such fact for each person who has both an age record and a sex record.

Example: Given the following database

```
person_age(chris, 25). % Yeah, right...
person_sex(chris, male).
person_age(louise, 8).
person_sex(louise, female).
```

combine should produce these additional facts:

```
person_full(chris, 25, male).
person_full(louise, 8, female).
```

Write a Prolog procedure which reverses the order of Johns children in the database. For example, given the following database

child(mary, john).
child(jane, john).
child(bill, john).

the goal ?- reversefacts. should change it to

child(bill, john). child(jane, john). child(mary, john). Write a Prolog procedure to assemble a list of someone's children from the facts in the database. The database should remain unchanged. Example:

```
child(mary, john).
child(jane, john).
child(bill, john).
```

```
?- assemble(john, L).
L = [mary, jane, bill]
```

?- bagof(X, Y^append(X, Y, [1,2,3,4]), Xs).

?- L=[1,2], member(X, L), delete(X, Y, L).

?- member(X, [a,b,c]), member(Y, [a,b,c]), !, X \= Y.

Problem XIX

Given the following Prolog database

balance(john, 100).
balance(sue, 200).
balance(mary, 100).
balance(paul, 500).

list all the results of these Prolog queries:

- I ?- bagof(Name, balance(Name, Amount), Names).
- ?- bagof(Name, Amount^{balance}(Name, Amount), Names).
- ?- bagof(Name, Name^balance(Name, Amount), Names).

Describe (in English) what the following predicate does:

```
% Both arguments to bbb are lists.
bbb([], []).
bbb(A, [X|F]) :- append(F, [X], A).
```

Given the following program

a(1,2). a(3,5). a(R, S) :- b(R, S), b(S, R). b(1,3). b(2,3). b(3, T) :- b(2, T), b(1, T).

list the first answer to this query:

```
?-a(X, Y), b(X, Y)
```

Will there be more than one answer?

Given the following definitions:

```
f(1, one).
f(s(1), two).
f(s(s(1)), three).
f(s(s(s(X))), N) :- f(X, N).
```

what are the results of these queries? If there is more than one possible answer, give at least two.

- ?- f(s(1), A).
- 2 ?- f(s(s(1), two).
- 3 ?- f(s(s(s(s(s(1))))), C).
- 9 ?- f(D, three).

Write a Prolog predicate sum_abs_diffs(List1, List2, Diffs) which sums the absolute differences between two integer lists of the same length. Example:

Write a Prolog predicate transpose(A, AT) which transposes a rectangular matrix given in row-major order. Example:

```
?- transpose([[1, 2], [3, 4]], AT).
        AT = [[1, 3], [2, 4]]
```

Write Prolog predicates that given a database of countries and cities

% country(name, population (in thousands), % capital). country(sweden, 8823, stockholm). country(usa, 221000, washington). country(france, 56000, paris). % city(name, in_country, population). city(lund, sweden, 88). city(paris, usa, 1). % Paris, Texas. Answer the following queries:

- Which countries have cities with the same name as capitals of other countries?
- 2 In how many countries do more than $\frac{1}{3}$ of the population live in the capital?
- Which capitals have a population more than 3 times larger than that of the secondmost populous city?

Problem XXV...

%country(name, population (in thousands), capital). country(sweden, 8823, stockholm). country(usa, 221000, washington). country(france, 56000, paris). country(denmark, 3400, copenhagen). % city(name, in_country, population). city(lund, sweden, 88). city(new_york, usa, 5000). % Paris, Texas. city(paris, usa, 1). % Paris, Texas. city(copenhagen, denmark, 1200). city(aarhus, denmark, 330). city(odense, denmark, 120). city(stockholm, sweden, 1300). city(gothenburg, sweden, 350). city(washington, usa, 3400). city(paris, france, 2000).

Write a Prolog predicate that extracts all words immediately following "the" in a given list of words. Example:

Write a Prolog predicate dup that duplicates each element of a list. Example:

The following Prolog program evaluates constant expressions:

```
eval(A+B, V) :- eval(A, V1), eval(B, V2),
V is V1 + V2.
```

```
eval(A*B, V) :- eval(A, V1), eval(B, V2),
V is V1 * V2.
```

```
eval(X, X) :- integer(X).
```

```
?- eval(3*4+5, V).
V = 17
```

Modify the program so that it allows the expression to contain variables. Variable values should be taken from an environment (a list of variable/value pairs), like this:

Write a predicate mult which, for all pairs of numbers between 0 and 9, adds their product to the Prolog database. I.e., the following facts should be asserted:

times(0, 0, 0). % 0 * 0 = 0times(0, 1, 0). % 0 * 1 = 0... times(9, 7, 63). % 9 * 7 = 63times(9, 8, 72). % 9 * 8 = 72times(9, 9, 81). % 9 * 9 = 81

The interaction should be as follows:

```
?- times(5,5,X).
no
?- mult.
yes
?- times(5,5,X).
X=25
```

Use a 2nd-order-predicate to write a predicate alltimes(L) which, given the times(X, Y, Z) database above produces a list of all the multiplication facts:

?- alltimes(L).
L = [1*1=2,1*2=2,1*3=3,...,9*9=81].

Show the results (yes/no) and resulting variable bindings for the following queries:

Given this Prolog predicate definition

```
mystery(L, B) :-
  member(X, L),
  append(A,[X],L),
  append(B,C,A),
  length(B,BL),
  length(C,CL),
  BL > CL.
```

what does the query

```
| ?- mystery([1,2,3,4,5],C), write(C), nl, fail.
print?
```
