# Compiler Phases

# Compiler Phases – Lexical analysis

- The lexer reads the source file and divides the text into lexical units (tokens), such as:
  - Reserved words **BEGIN, IF,...**
  - identifiers `x, StringTokenizer,...`
  - special characters `+, *, -, ^, ...`
  - numbers `30, 3.14, ...`
  - comments `(* text *)`,
  - strings `"text"`.
- Lexical errors (such as 'illegal character', 'undelimited character string', 'comment without end') are reported.

## Lexical Analysis of English

- The sentence

"The boy's cowbell won't play."

would be translated to the list of tokens

the, boy+possessive, cowbell, will, not, play

## Lexical Analysis of Java

- The sentence

"x = 3.14 \* (9.0+y);"

would be translated to the list of tokens

<ID,x>, EQ, <FLOAT,3.14>, STAR, LPAREN,  
<FLOAT,9.0>, PLUS, <ID,y>, RPAREN, SEMICOLON

## Example – Lexical Analysis

- Break up the source code (a text file) and into tokens.

Source Code	Stream of Tokens
PROCEDURE Foo ();	PROCEDURE, <id, Foo>, LPAR, RPAR, SC,
VAR i : INTEGER;	VAR, <id, i>, COLON, <id, INTEGER>, SC,
BEGIN	BEGIN, <id, i>, CEQ, <int, 1>, SC,
i := 1;	WHILE, <id, i>, LT, <int, 20>, DO,
WHILE i < 20 DO	PRINT, <id, i>, MUL, <int, 2>, SC,
PRINT i * 2;	<id, i>, CEQ, <id, i>, MUL, <int, 2>, PL
i := i * 2 + 1;	<int, 1>, SC, ENDDO, SC, END, <id, Foo>
ENDDO;	
END Foo;	

# Problems

# Free vs. Fixed Format

- Most languages are **free format**, i.e. it does not matter where on a line of text a certain token occurs.
- FORTRAN (at least early versions) uses a **fixed** format where the first 6 characters on the input line is a label, and the last characters (columns 72-80) a comment.
- A "C" in the first column indicates a **comment line**.
- Any character in column 6 indicates a **continuation line**.

C      Compute the determinant:

```
det = a(1,1) * a(2,2) * a(3,3) + a(1,2) * a(2,3) * a(3,1)
&      + a(2,1) * a(3,2) * a(1,3) - a(3,1) * a(2,2) * a(1,3)
&      - a(2,1) * a(1,2) * a(3,3) - a(1,1) * a(3,2) * a(2,3)
```

## Free vs. Fixed Format...

- Python, Occam, and some functional languages use indentation to indicate nesting:

```
def quicksort(list, start, end):  
    if start < end:  
        split = partition(list, start, end)  
        quicksort(list, start, split-1)  
        quicksort(list, split+1, end)  
    else:  
        return
```

# Whitespace

In most modern languages whitespace (blanks and tabs) are significant. FORTRAN and Algol-68 are different: whitespace may be added anywhere to improve readability. The FORTRAN statement

```
D0 5 I = 1.25
```

is an assignment statement, meaning the same as:

```
D05I = 1.25
```

This statement, on the other hand, is a loop statement:

```
D0 5 I = 1,25  
  . . .  
5 CONTINUE
```

# Whitespace. . .

*An error in a single FORTRAN statement resulted in the loss of the first American probe to Venus (the Mariner I).*

```
.....  
DO 5 K = 1. 3  
T(K) = W0  
Z = 1.0/(X**2)*B1**2+3.0977E-4*B0**2  
D(K) = 3.076E-2*2.0*(1.0/X*B0*B1+3.0977E-4*  
*(B0**2-X*B0*B1))/Z  
E(K) = H**2*93.2943*W0/SIN(W0)*Z  
H = D(K)-E(K)  
5 CONTINUE
```

This is now considered an urban legend.

# Buffering

- If done incorrectly, lexical analysis can be an expensive phase of the compiler – It is the only phase which actually considers each and every character of the program.
- It is, for example, crucial not to read one character at a time from the input file. Rather, a large block of the input text file must be read and put into a **buffer**. This buffer is then used to provide the lexer with characters.
- Sometimes the lexer may also need to look ahead at characters to come before deciding on what token appears next in the text. The buffer is useful in such circumstances also.

# Keywords

- Most languages have **reserved** keywords, which means that these words may not be redefined by the user.
- PL/I does **not** reserve keywords which makes it difficult for the lexer to distinguish between user-defined identifiers and keywords:

```
IF THEN THEN THEN = ELSE; ELSE ELSE = THEN;
```

# Error handling

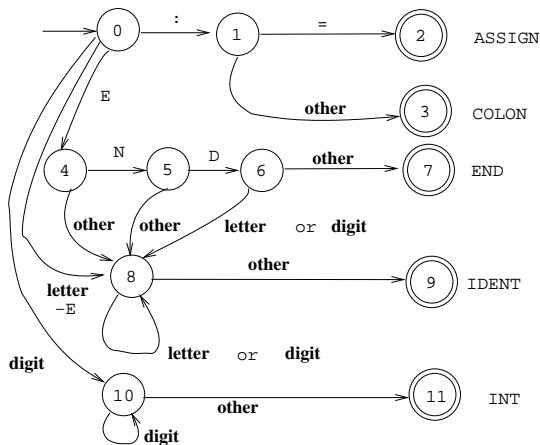

- What do we do when an error is encountered during lexical analysis?
  - Panic** Skip characters until a well-formed token is found.
  - Replace** Replace an incorrect character.
  - Delete** Delete an incorrect character.
  - Insert** Insert a missing character.
  - Transpose** Switch two characters.

# Communication

- The Lexer may communicate with the parser in many different ways.
- Lexical analysis might, for example, run as a special pass writing the tokens on a temporary file which is read by the parser.
- Or – and this is probably the most common situation – the parser makes a procedure call to the lexer whenever a token is needed.
- The Lexer and the Parser could also run as two concurrent processes communicating over a pipe.

# Transition Diagrams

# Transition Diagrams

```

TYPE TokenType = (Assign, End, ...);
VAR  s          : (State0, State1, ...);
     c          : CHAR;
PROCEDURE GetToken () : TokenType;
  CASE s OF
    State0 : c := NextChar();
             CASE c OF
               ":"          : s := State1|
               "E"         : s := State4|
               "0" .. "9" : s := State10|
               ELSE        : s := State8
             END|
    State1 : c := NextChar();
             IF c="=" THEN s := State2
             ELSE        s := State3 END|

```

```
State2 : RETURN Assign|
State3 : PutChar(c); RETURN Colon|
State4 : c := NextChar();
        IF c = "N" THEN s := State5
        ELSE           s := State8 END|
State5 : c := NextChar();
        IF c = "D" THEN s := State6
        ELSE           s := State8 END|
State6 : c := NextChar();
        IF IsLetterOrDigit(c)
        THEN s := State8
        ELSE s := State7 END;|
State7 : PutChar(c); RETURN End|
```

```
State8 : c := NextChar();
        IF NOT IsLetterOrDigit(c)
        THEN s := State9 END|
State9 : PutChar(c); RETURN Ident|
State10 : c := NextChar();
         IF NOT IsDigit(c)
         THEN s := State11 END|
State11 : PutChar(c); RETURN Int|
END;
END GetToken;
```

# Regular Grammars and Lexical Analysis

# Regular Grammars

- A grammar is **regular** if all rules are of the form

$$A \rightarrow aB$$

$$A \rightarrow a$$

- By convention, the symbols  $A, B, C, \dots$  are non-terminals,  $a, b, c, \dots$  are terminals, and  $\alpha, \beta, \gamma, \dots$  are strings of symbols.
- Regular grammars are used to describe the lexical structure of programs, i.e. what tokens look like.

# Regular Grammars...

- The following grammar describes C identifiers:

$\text{id} \rightarrow \underline{\text{letter}} \mid \underline{\text{letter}} S$

$S \rightarrow \underline{\text{letter}} \mid \underline{\text{letter}} S$

$S \rightarrow \underline{\text{digit}} \mid \underline{\text{digit}} S$

$\underline{\text{digit}} \rightarrow 0 \mid 1 \mid \dots \mid 9$

$\underline{\text{letter}} \rightarrow A \mid \dots \mid Z \mid$

$a \mid \dots \mid z$

- Here's a derivation of the identifier cow5:

$\text{id} \Rightarrow \underline{\text{letter}} S \Rightarrow c S \Rightarrow c \underline{\text{letter}} S \Rightarrow c o S \Rightarrow$

$c o \underline{\text{letter}} S \Rightarrow c o w S \Rightarrow c o w \underline{\text{digit}} \Rightarrow \underline{\text{cow5}}$

# Regular Grammars. . .

- This is a grammar for floating point numbers. As written, it is not quite regular: We treat digit as a terminal.

float  $\rightarrow$   $\pm$  float1 |  $-$  float1 | float1  
float1  $\rightarrow$  digit float1 | float2  
float2  $\rightarrow$   $\cdot$  float3  
float3  $\rightarrow$  digit float4 | digit  
float4  $\rightarrow$  digit float4 | float5  
float5  $\rightarrow$  E float6  
float6  $\rightarrow$   $\pm$  float7 |  $-$  float7 | float7  
float7  $\rightarrow$  digit float7 | digit

Use the grammar on the previous slide to derive 0.5E+7.

float  $\Rightarrow$  float1  $\Rightarrow$  digit float1  
 $\Rightarrow$  0 float1  
 $\Rightarrow$  0 float2  
 $\Rightarrow$  0. float3  
 $\Rightarrow$  0. digit float4  
 $\Rightarrow$  0. 5 float4  
 $\Rightarrow$  0. 5 float5  
 $\Rightarrow$  0. 5 E float6  
 $\Rightarrow$  0. 5 E + float7  $\Rightarrow$  0. 5 E + 7

# Regular Expressions

# Regular Expressions

Regular expressions (REs) have the same expressive power as regular grammars. An RE for FP numbers:

$$(\backslash+ | \backslash-)?\text{digit} * \backslash.\text{digit} + (\text{E}(\backslash+ | \backslash-)?\text{digit}+)?$$

RE	Matches
character	The character.
$e_1   e_2$	$S$ , if $S$ is matched by $e_1$ or $e_2$ .
$e_1 e_2$	$S_1 S_2$ , if $e_1$ matches $S_1$ and $e_2$ matches $S_2$ .
$e+$	One or more $S$ if $S$ is matched by $e$ .
$e^*$	Zero or more $S$ if $S$ is matched by $e$ .
$e?$	Zero or one $S$ if $S$ is matched by $e$ .
$(e)$	$S$ , if $S$ is matched by $e$ .
$\backslash e$	$S$ , if $S$ is matched by $e$ .

# Regular Expression Examples

EXPRESSION	MATCHES
$a$	'a'.
$[a - z]$	'a', 'b', ..., 'z'.
$[a - zA - Z0 - 9]$	'a', 'b', ..., 'z', 'A', 'B', ..., 'Z', '0', '1', ..., '9', .
$[a - zA - Z0 - 9]^*$	Zero or more letters or digits.
$(a   b+)?$	“, 'a', 'b', 'bb', 'bbb', ....
$(a   b+)?(cd)^*$	“, 'a', 'b', 'bb', 'bbb', ..., 'acd', 'bcd', 'cdcd', ....

# The Chomsky Hierarchy

TYPE	GRAMMAR	PSR
0	Unrestricted	$\alpha \rightarrow \beta$
1	Context Sensitive	$\alpha \rightarrow \beta,$ $ \alpha  \leq  \beta $
2	Context Free	$A \rightarrow \beta$
3	Regular	$A \rightarrow a\beta$ $A \rightarrow a$

# The Chomsky Hierarchy...

- Regular languages are less powerful than context free languages.
- Languages are organized in **the Chomsky Hierarchy** according to their generative power.
- Type 3 languages are more restrictive (can describe simpler languages than) type 2 languages.
- Type 3 languages can be parsed in linear time, type 2 languages in cubic time.
- Programming languages are in between type 2 and 3.
- Two natural languages (Swiss German and Bambara) are known not to be context free.

# DFA

# Finite Automata

- Here's a **transition diagram** describing Pascal identifiers:

- Circles represent **states**. They represent how much of the input string we have processed.
- Arrows represent **transitions** from one state to the next, when the character labeling the arrow is matched.
- State 1 is the **start state**.
- Accepting states** are represented by double circles.

# Finite Automata...

- Parsing a string of characters using this transition diagram can be indicated by listing the states and transitions used:

$$\rightarrow 1 \xrightarrow{t} 2 \xrightarrow{m} 2 \xrightarrow{p} 2 \xrightarrow{8} 2$$

- This shows that the string of characters "tmp8" form a legal Pascal identifier.

- A **Deterministic Finite Automaton**  $M$  consists of
  - An alphabet  $\Sigma$ ,
  - A set of states  $S$ ,
  - A transition function  $T : S \times \Sigma \rightarrow S$ ,
  - A start state  $s_0 \in S$ ,
  - A set of accepting states  $A \subset S$ .
- $T$  records the transitions between states, depending on input:

# DFA Error States

- The transition function  $T : S \times \Sigma \rightarrow S$  is a **function**. Hence  $T(s, c)$  must be defined for every state  $s$  and character  $c$ .
- But we have ignored any erroneous input. We should have said

but this would be tedious. Instead, we normally assume that these error transitions always exist.

# Examples

- Strings with exactly **one** b:

- Strings with **at most one** (i.e. 0 or 1) b:

# Floating Point Literals

- Transition diagram for natural numbers:

- Transition diagram for signed natural numbers:

- Transition diagram for signed real numbers:

- Transition diagram for FP numbers:

# C Comments

- C comments are of the form

`/* ... (no */s) ... */`

- Here's the corresponding transition diagram:

# Lookahead

- The end of an identifier is reached when the next character is not a letter or digit.
- The string "tmp8\*hi;" has two identifiers, terminated by "\*" and ";", respectively.
- Here's the corresponding transition diagram:

- [other] means that we're expecting some other character (not letter or digit) as **lookahead**.

# Towards an NFA

- Here are transition diagrams for recognizing `:=`, `<=`, and `=`:

# Towards an NFA...

- But, we'd like just **one** start state, since, at any time during parsing, any token could occur:

- What if two tokens start with the same character? Note that this is not a DFA since there are three transitions on the same character:

- We can break out the offending character:

## Towards an NFA...

- But, this factoring of states becomes tedious. Instead we can construct a **Nondeterministic Finite Automaton** (NFA), by adding  $\epsilon$ -transitions:

# $\epsilon$ -Transitions

- An  $\epsilon$ -transition occurs without consulting the input and without consuming any characters:

- A **Nondeterministic Finite Automaton**  $M$  consists of
  - An alphabet  $\Sigma$ ,
  - A set of states  $S$ ,
  - A transition function  $T : S \times (\Sigma \cup \{\epsilon\}) \rightarrow \mathbb{P}(S)$ ,
  - A start state  $s_0 \in S$ ,
  - A set of accepting states  $A \subset S$ .
- $\mathbb{P}(S)$  is the **power-set** of  $S$ , the set of all subsets of  $S$ .
- On any transition, we can go to a **set of states**:

$$T(x, c) = \{y, z\}$$

# NFA Example

- Consider the following NFA transition diagram:

- abb is accepted by these moves:  $\rightarrow 1 \xrightarrow{a} 2 \xrightarrow{b} 4 \xrightarrow{\epsilon} 2 \xrightarrow{b} 4$
- or by these moves:  $\rightarrow 1 \xrightarrow{a} 3 \xrightarrow{\epsilon} 4 \xrightarrow{\epsilon} 2 \xrightarrow{b} 4 \xrightarrow{\epsilon} 2 \xrightarrow{b} 4$
- The NFA accepts  $ab^+ | ab^* | b^*$ , or, simpler,  $(a | \epsilon)b^*$ .
