Superoperators in Interpreters

Sam Martin January 27 2011

#### Important Questions

What do we care about with interpreters? How can we make programs take less space?

Hybrid translator/interpreter Input: ANSI C Outputs: SPARC and MIPS R3000 Written in Assembly

Hybrid translator/interpreter Input: ANSI C Outputs: SPARC and MIPS R3000 Written in Assembly why?

## Superoperators

$$x^{*2} + 1$$
  
 $z^{*3} + 1$   
 $y + 5$   
 $x^{*2} + 1$   
 $t + t + x$   
 $x^{*2} + 1$ 

#### How much slower can we expect interpreted code

#### How much slower can we expect interpreted code Around 8 to 16 times slower (eep)

#### How much slower can we expect interpreted code Around 8 to 16 times slower (eep) What if we use superoperators?

#### How much slower can we expect interpreted code Around 8 to 16 times slower (eep) What if we use superoperators? Only 3 to 9 times slower (yay!)

hti actually compiles function prologues hti uses the output of lcc's intermediate representation lcc produces Syntax Trees How many evaluation stacks does hti use?

# Room for Superoperators

Icc only produces 109 operators in its standard trees We have enough room for 147 Superoperators now (256-109) Can we make more room?

## Optimizations

What do we optimize for...

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

## Optimizations

What do we optimize for... Size?

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

## Optimizations

What do we optimize for... Size? Time?

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

#### We can eliminate opcodes that are never used in a particular program Now we have more possibilities for Superoperators Drawbacks?

#### Questions?
